GETIFADDRS(3)

Linux Programmer's Manual

GETIFADDRS(3)

NAME top

getifaddrs, freeifaddrs - get interface addresses

SYNOPSIS top

```
#include <sys/types.h>
#include <ifaddrs.h>
int getifaddrs(struct ifaddrs **ifap);
void freeifaddrs(struct ifaddrs *ifa);
```

DESCRIPTION top

The **getifaddrs**() function creates a linked list of structures describing the network interfaces of the local system, and stores the address of the first item of the list in *ifap. The list consists of ifaddrs structures, defined as follows:

```
struct ifaddrs {
   struct ifaddrs
                                /* Next item in list */
                   *ifa next;
                   *ifa_name; /* Name of interface */
                    ifa_flags; /* Flags from SIOCGIFFLAGS */
   unsigned int
   struct sockaddr *ifa addr; /* Address of interface */
   struct sockaddr *ifa_netmask; /* Netmask of interface */
   union {
       struct sockaddr *ifu broadaddr;
                        /* Broadcast address of interface */
       struct sockaddr *ifu dstaddr;
                        /* Point-to-point destination address */
    } ifa ifu;
#define
                    ifa broadaddr ifa ifu.ifu broadaddr
#define
                    ifa dstaddr ifa ifu.ifu dstaddr
   void
                                 /* Address-specific data */
                   *ifa data;
};
```

The *ifa_next* field contains a pointer to the next structure on the list, or NULL if this is the last item of the list.

The ifa name points to the null-terminated interface name.

The *ifa_flags* field contains the interface flags, as returned by the **SIOCGIFFLAGS ioctl**(2) operation (see netdevice(7) for a list of these flags).

The *ifa_addr* field points to a structure containing the interface address. (The *sa_family* subfield should be consulted to determine the format of the address structure.) This field may contain a null

pointer.

The *ifa_netmask* field points to a structure containing the netmask associated with *ifa_addr*, if applicable for the address family. This field may contain a null pointer.

Depending on whether the bit **IFF_BROADCAST** or **IFF_POINTOPOINT** is set in *ifa_flags* (only one can be set at a time), either *ifa_broadaddr* will contain the broadcast address associated with *ifa_addr* (if applicable for the address family) or *ifa_dstaddr* will contain the destination address of the point-to-point interface.

The *ifa_data* field points to a buffer containing address-family-specific data; this field may be NULL if there is no such data for this interface.

The data returned by **getifaddrs**() is dynamically allocated and should be freed using **freeifaddrs**() when no longer needed.

RETURN VALUE top

On success, **getifaddrs**() returns zero; on error, -1 is returned, and *errno* is set appropriately.

ERRORS top

getifaddrs() may fail and set errno for any of the errors specified
for socket(2), bind(2), getsockname(2), recvmsg(2), sendto(2),
malloc(3), or realloc(3).

VERSIONS top

The **getifaddrs**() function first appeared in glibc 2.3, but before glibc 2.3.3, the implementation supported only IPv4 addresses; IPv6 support was added in glibc 2.3.3. Support of address families other than IPv4 is available only on kernels that support netlink.

ATTRIBUTES top

For an explanation of the terms used in this section, see attributes(7).

Interface		Attribute	Value
getifaddrs(),	freeifaddrs()	Thread safety	MT-Safe

CONFORMING TO top

Not in POSIX.1. This function first appeared in BSDi and is present on the BSD systems, but with slightly different semantics documented—returning one entry per interface, not per address. This means ifa addr and other fields can actually be NULL if the interface has

no address, and no link-level address is returned if the interface has an IP address assigned. Also, the way of choosing either *ifa broadaddr* or *ifa dstaddr* differs on various systems.

NOTES top

The addresses returned on Linux will usually be the IPv4 and IPv6 addresses assigned to the interface, but also one AF_PACKET address per interface containing lower-level details about the interface and its physical layer. In this case, the <code>ifa_data</code> field may contain a pointer to a <code>struct rtnl_link_stats</code>, defined in <code><linux/if_link.h></code> (in Linux 2.4 and earlier, <code>struct net_device_stats</code>, defined in <code><linux/netdevice.h></code>), which contains various interface attributes and <code>statistics</code>.

EXAMPLE tor

The program below demonstrates the use of **getifaddrs()**, **freeifaddrs()**, and **getnameinfo(3)**. Here is what we see when running this program on one system:

```
$ ./a.out
         AF PACKET (17)
10
                tx packets =
                                     524; rx packets =
                                                               524
                tx bytes =
                                   38788; rx bytes
                                                            38788
wlp3s0
         AF PACKET (17)
                tx packets =
                                 108391; rx packets =
                                                           130245
                                30420659; rx bytes
                tx bytes =
                                                         94230014
em1
         AF PACKET (17)
                tx packets =
                                       0; rx packets =
                                                                 0
                tx bytes
                                       0; rx bytes
                                                                 0
10
         AF INET (2)
                address: <127.0.0.1>
         AF INET (2)
wlp3s0
                address: <192.168.235.137>
10
         AF INET6 (10)
                address: <::1>
         AF INET6 (10)
                address: <fe80::7ee9:d3ff:fef5:1a91%wlp3s0>
```

Program source

```
if (getifaddrs(&ifaddr) == -1) {
               perror("getifaddrs");
               exit(EXIT FAILURE);
           }
           /* Walk through linked list, maintaining head pointer so we
              can free list later */
           for (ifa = ifaddr, n = 0; ifa != NULL; ifa = ifa->ifa next, n++) {
               if (ifa->ifa addr == NULL)
                   continue;
               family = ifa->ifa addr->sa family;
               /* Display interface name and family (including symbolic
                  form of the latter for the common families) */
               printf("%-8s %s (%d)\n",
                      ifa->ifa name,
                      (family == AF PACKET) ? "AF PACKET" :
                      (family == AF_INET) ? "AF_INET" :
                      (family == AF INET6) ? "AF INET6" : "???",
                      family);
               /* For an AF_INET* interface address, display the address */
               if (family == AF INET || family == AF INET6) {
                   s = getnameinfo(ifa->ifa addr,
                           (family == AF INET) ? sizeof(struct sockaddr in) :
                                                  sizeof(struct sockaddr in6),
                           host, NI MAXHOST,
                           NULL, 0, NI NUMERICHOST);
                   if (s != 0) {
                       printf("getnameinfo() failed: %s\n", gai strerror(s));
                       exit(EXIT FAILURE);
                   }
                   printf("\t\taddress: <%s>\n", host);
               } else if (family == AF PACKET && ifa->ifa data != NULL) {
                   struct rtnl link stats *stats = ifa->ifa data;
                   printf("\t\ttx packets = %10u; rx packets = %10u\n"
                          "\t\ttx bytes = 10u; rx bytes = 10u",
                          stats->tx packets, stats->rx packets,
                          stats->tx bytes, stats->rx bytes);
               }
           freeifaddrs(ifaddr);
           exit(EXIT SUCCESS);
       }
